

1 ABSTRACT

2

3 A spa cover lifter comprising opposing left and right

4 side arm supports spaced apart to receive opposing left and

5 right cover side surfaces between the same. Each side arm

6 support has an upper end adapted to rotatably support a

7 portion of the spa cover and an opposing lower end. Each

8 side arm support is rotatably mounted to a spa side.

9 Extending from the right side arm support, around the back

10 spa side, to the opposing left side arm support is a lower

11 linking member having opposing ends spaced apart to

12 pivotally attach to the respective spaced apart left and

13 right side arm supports. The linking member can pivot

14 relative to the side arms, about a substantially horizontal

15 axis to define a linking member pivot angle which is the

16 angle between each side arm support and the linking member.

17 The pivotal attachment point of the lower linking member to

18 the respective side arm support is adjacent the respective

19 lower end thereof. To maintain the relative angle between

20 each side arm support and the linking member, an adjustable

21 bracing extends between each side arm support and the

22 linking member. The relative position between each side arm

23 support and the linking member is adjustable.
